How do you calculate the energy stored in a coil?

The energy stored in a coil can be calculated using the formula $E = \frac{1}{2} * L * I^2$, where E is the energy, L is the inductance, and I is the current flowing through the coil. For example, in a coil of resistance 5 Ω and inductance 4 H connected to a 10 V battery, the energy stored in the coil can be found by first calculating the current flowing through the coil.

Superconducting energy storage coils form the core component of SMES, operating at constant temperatures with an expected lifespan of over 30 years and boasting up to 95% energy storage efficiency - originally proposed by Los Alamos National Laboratory (LANL). Since its conception, this structure has become widespread across device research.
