

How does a superconducting coil store energy?

A superconducting coil stores energy in the form of a magnetic field generated by a circulating current. The maximum stored energy is determined by two factors: the size and geometry of the coil, which determines its inductance, and the current flowing through the coil. The larger the coil and the higher the current, the greater the stored energy.

How do you calculate the energy stored in a coil?

The energy stored in a coil can be calculated using the formula  $E = \frac{1}{2} * L * I^2$ , where  $E$  is the energy,  $L$  is the inductance, and  $I$  is the current flowing through the coil. For example, in a coil of resistance 50 and inductance 4 H connected to a 10 V battery, the energy stored in the coil can be found by first calculating the current flowing through the coil.

What is a SMEs coil?

Abstract: This paper presents an SMES coil which has been designed and tested by University of Cambridge. The design gives the maximum stored energy in the coil which has been wound by a certain length of second-generation high-temperature superconductors (2G HTS).

What is a second-generation high-temperature superconductors (HTS) coil?

The design gives the maximum stored energy in the coil which has been wound by a certain length of second-generation high-temperature superconductors (2G HTS). A numerical model has been developed to analyse the current density and magnetic field distribution and calculate the AC losses during the charge and discharge process of the coil.
