

How does a water storage system work?

The inflowing water drives a turbine and a generator that feeds electricity into the grid. This represents the discharging phase of the storage system. Recharging is achieved by pumping the water out of the sphere against the surrounding water pressure using energy from the grid.

How is water pressure used at the seabed?

What is deep sea pumped hydro storage?

Deep sea pumped hydro storage is a novel approach towards the realization of an offshore pumped hydro energy storage system (PHES), which uses the pressure in deep water to store energy in hollow concrete spheres. The spheres are installed at the bottom of the sea in water depths of 600 m to 800 m.

How does pumped hydro energy storage work?

For example, with pumped hydro energy storage, water is pumped from a lake to another, higher lake when there's extra electricity and released back down through power-generating turbines when more electricity is needed. But that approach is limited by geography, and most potential sites in the United States have already been used.

How do energy storage spheres re-charge?

In order to re-charge the storage system, the water is pumped out of the sphere against the pressure of the surrounding water column. A schematic cross-sectional view of an energy storage sphere is presented in Fig. 1.
