How do adsorption thermochemical heat storage systems work?

In a typical adsorption thermochemical heat storage system, an adsorbent thermochemical material captures moisture to release thermal energy and subsequently requires regeneration and dehydration when exposed to a heat source such as solar thermal to store the excessive solar thermal energy for daily or for seasonal thermal storage applications.

What is the adsorption capacity of honeycomb zeolites?

Jänchen et al. numerically investigated the reactor performance on the filled with particles and honeycomb zeolites through CFD modelling, the honeycomb structure achieved the adsorption capacity up to 0.205 g/g, shorten discharging reaction time and high air temperature lift.

What is the air velocity distribution of a honeycomb channel?

For three different air velocity distribution schematics, the air velocity of central area in the single triangular honeycomb channel shows a higher value than that of air-zeolite interface, the maximum and minimum values are 1.8 m/s for central area and 0.069 m/s for air-zeolite interface, respectively.

What is the air temperature lift for a triangular honeycomb reactor?

The air temperature lift for the triangular honeycomb reactor typically falls within the range of 25 °C-33 °C, showcasing superior performance compared to cascade reactors and comparable competitiveness with rotating drum and net-packed reactors.
