What is a hybrid power generation system (HPGS)?

It also opens up possibilities for the large-scale integration of wind power and solar power into the grid [4, 5]. The hybrid power generation system (HPGS) is a power generation system that combines high-carbon units (thermal power), renewable energy sources (wind and solar power), and energy storage devices.

Does a wind-solar-thermal-storage hybrid power generation system need a coupling?

This paper considers the complementary capacity planning of a wind-solar-thermal-storage hybrid power generation system under the coupling of electricity and carbon cost markets. It proposes a method for establishing scenarios of electricity-carbon market coupling to explore the role of this coupling in power generation system capacity planning.

What is the contribution of thermal energy storage?

Besides the well-known technologies of pumped hydro, power-to-gas-to-power and batteries, the contribution of thermal energy storage is rather unknown. At the end of 2019 the worldwide power generation capacity from molten salt storage in concentrating solar power (CSP) plants was 21 GWh el.

Can energy storage reduce wind curtailment?

In addition to this, energy storage systems can help in reducing wind curtailment. The major factor that influences wind curtailments in the real market dispatch is the level of system non-synchronous penetration (SNSP). The TSOs in Ireland aim to allow 75% SNSP in the future system.

What is a thermal energy storage system?

In other words, the thermal energy storage (TES) system corrects the mismatch between the unsteady solar supply and the electricity demand. The different high-temperature TES options include solid media (e.g., regenerator storage), pressurized water (or Ruths storage), molten salt, latent heat, and thermo-chemical [2].

Fig. 5, Fig. 6, Fig. 7 show the low wind power, median wind power and high wind power generation mix as optimised for each scenario in years 2010, 2015 and 2020 in variable expansion mode. In the low wind power scenarios A, B and C gas generation was selected to balance wind power variability and meet the deficit in demand.

Hot water energy storage wind power generation

Sensible storage of heat and cooling uses a liquid or solid storage medium with high heat capacity, for example, water or rock. Latent storage uses the phase change of a material to absorb or release energy. Thermochemical storage stores energy as either the heat of a reversible chemical reaction or a sorption process.

A significant mismatch between the total generation and demand on the grid frequently leads to frequency disturbance. It frequently occurs in conjunction with weak protective device and system control coordination, inadequate system reactions, and insufficient power reserve [8]. The synchronous generators' (SGs') rotational speeds directly affect the grid ...

Indirect liquid cooling is a heat dissipation process where the heat sources and liquid coolants contact indirectly. Water-cooled plates are usually welded or coated through thermal conductive silicone grease with the chip packaging shell, thereby taking away the heat generated by the chip through the circulated coolant [5]. Traditionally, heat storage has been in the form of sensible heat, raising the temperature of a medium. Examples of such energy storage include hot water storage (hydro-accumulation), underground thermal energy storage (aquifer, borehole, cavern, ducts in soil, pit) [36], and rock filled storage (rock, pebble, gravel). Latent heat storage is a ...
