

What is reversible solid-state hydrogen storage of magnesium hydride?

Anyone you share the following link with will be able to read this content: Provided by the Springer Nature SharedIt content-sharing initiative Reversible solid-state hydrogen storage of magnesium hydride, traditionally driven by external heating, is constrained by massive energy input and low systematic energy density.

Can magnesium hydride be used for hydrogen storage?

A collaborative effort between Swiss and Polish experimental and theoretical physicists has uncovered why past efforts to utilize magnesium hydride for hydrogen storage haven't met expectations - and why future attempts might be successful. Hydrogen has long been seen as the energy carrier of the future.

What is magnesium hydride based on?

Magnesium (Mg), as one of the most abundant light metal elements on Earth, can react with hydrogen to form magnesium hydride (MgH_2), which can be decomposed into Mg and H_2 at high temperatures. The hydrogen storage system based on Mg/ MgH_2 demonstrates notable attributes such as a broad range of raw material sources and cost-effectiveness.

Are metal hydrides suitable for hydrogen energy storage?

Metal hydrides (MH) are known as one of the most suitable material groups for hydrogen energy storage because of their large hydrogen storage capacity, low operating pressure, and high safety. However, their slow hydrogen absorption kinetics significantly decreases storage performance.

Can magnesium hydride be used as an energy carrier?

Magnesium hydride (MgH_2) offers a wide range of potential applications as an energy carrier due to its advantages of low cost, abundant supplies, and high energy storage capacity. Energy storage is the key for large-scale application of renewable energy, however, massive efficient energy storage is very challenging.

Is magnesium hydride stable?

Magnesium hydride (MgH_2) has attracted significant attention due to its 7.6 wt% hydrogen content and the natural abundance of Mg. However, bulk MgH_2 is stable ($\Delta H_f \sim -76 \text{ kJ mol}^{-1}$) and releases hydrogen only at impractically high temperatures ($> 300^\circ\text{C}$).
