

How is methane produced?

Process flexible operation achieved by a bidirectional connection with the grid. Energy- and cost-efficient production of methane in a continuous manner. Costs of methane in different scenarios range from 60 to 161.6 EUR/MWh. Power-to-methane (PtM) coupled with renewables requires an energy buffer to ensure a steady and flexible operation.

Does adsorbed natural gas store methane?

Adsorbed natural gas systems have the potential to store high densities of methane ( $\text{CH}_4$ , the principal component of natural gas) within a porous material at ambient temperature and moderate pressures [4].

How do you increase methane storage capacity?

One way of increasing methane storage capacity is to use tanks containing porous materials, such as metal-organic frameworks, as a storage medium. However, for every methane molecule adsorbed and desorbed there is an associated thermal fluctuation that could cause overheating or reduce storage efficiency if left unchecked.

How can energy be stored in a power plant?

There are various possibilities of storing this excess energy: A direct storage of the electrical energy can for instance be realized with supercapacitors and superconducting magnetic energy storage (SMES). By the use of pumped storage power plants, electric energy is converted to potential energy.

What is the penetration of renewables in methane production?

A renewables penetration of 92.4% was achieved for methane production with an LCOCH<sub>4</sub> of 181.12 EUR/MWh at  $L_{c,p} = 3,000$ . As  $L_{c,p}$  increases to more than 3,000 tonnes, the penetration of renewables and the ratio of renewable energy to the grid do not change noticeably.

How does power-to-methane work?

Power-to-Methane coupled with renewables via liquid CO<sub>2</sub> energy storage. Process flexible operation achieved by a bidirectional connection with the grid. Energy- and cost-efficient production of methane in a continuous manner. Costs of methane in different scenarios range from 60 to 161.6 EUR/MWh.
