Should residential Peak-Valley pricing policies be optimized?

The PVP policy needs to be optimized from the price and time period division. In order to deal with the rapid growth in residential electricity consumption, residential peak-valley pricing (PVP) policies have been implemented in 12 provinces in China. However, being inappropriate, the residential PVP policies have delivered no significant results.

Does PVP increase electricity price during peak periods?

This is because the optimized PVP policy increases the electricity price during peak periods. The current policies in Types I and II provinces are less effective in peak shaving, with only a 1.9%-3.2% reduction in peak load, while those in Type III provinces appear to be very effective in peak shaving.

How to improve peak-valley price mechanism?

1. Improve the peak-valley price mechanism. 1 Scientifically divide peak and valley periods. All localities should consider the local power supply-demand status, system power load characteristics, the proportion of new energy installed capacity, system adjustment capabilities, and other factors.

The economics of energy storage represents the decision of whether or not to invest in energy storage technologies. Unlike the feed-in-tariff (FIT), which is mainly determined by the supply and demand in the electricity market, the peak-valley spread is a reflection of the time differentials of electricity as a commodity [11].
