What is a server water cooled system?

Fig. 1 (a) shows the system flowchart. A server water-cooled system, including a cabinet, fin-type water-cooled heat sinks, two pumps, plate heat exchanger, and cooling tower, with a total load of 4.8 kW. The server cabinet contained 12 chips, with a thermal power of 400 W for each chip.

How does a server cooling water transfer heat?

The heat carried by the server cooling water is released to the cooling tower water in the heat exchanger first, and finally to the atmospheric environment. Therefore, more attention should be paid to the cooling-tower water mass flow rate and atmospheric conditions.

Can water-cooled heat sinks reduce energy consumption of data center?

In order to reduce the energy consumption of data center caused by cooling system, research on the water-cooled heat sinks used to cool chips has become increasingly important with the steep increase in the heat flux density of data centers.

Why is expanding the heat dissipation area important?

It was found that for a 350 kW water cooling system and a 50 kW air cooling system, the discounted payback period (DPB) was as low as 285 days.

How does humidity affect server water cooled systems?
