Typically, the storage capacity for hydrogen in light-duty vehicles should enable a driving range of more than 300 miles to meet consumer needs. Because hydrogen has a lower volumetric energy density than that of gasoline, storing this much hydrogen on a vehicle currently requires a larger tank at higher pressure than other gaseous fuels.

Grid-to-vehicle power or energy flows are referred to as "G2V" or "charging mode", while vehicle-to-power or energy flows are referred to as "V2G" or "discharging mode". Fig. 27 shows a V2G framework that has interactions among power system operators, consumers, and EV users. Here, these V2G systems can work in a G2V mode.
