What is compressed air energy storage (CAES)?

1. Introduction Compressed Air Energy Storage (CAES) has emerged as one of the most promising large-scale energy storage technologies for balancing electricity supply and demand in modern power grids. Renewable energy sources such as wind and solar power, despite their many benefits, are inherently intermittent.

Why is water injected into compressed air energy storage systems?

The presence of water in compressed air energy storage systems improves the efficiency of the system, hence the reason for water vapour being injected into the system [1]. This water vapour undergoes condensation during cooling in the heat exchangers or the thermal energy system [1].

Where can compressed air energy be stored?

The number of sites available for compressed air energy storage is higher compared to those of pumped hydro [1]. Porous rocks and cavern reservoirs are also ideal storage sites for CAES. Gas storage locations are capable of being used as sites for storage of compressed air.

How does a compressed air energy storage system work?

The performance of compressed air energy storage systems is centred round the efficiency of the compressors and expanders. It is also important to determine the losses in the system as energy transfer occurs on these components. There are several compression and expansion stages: from the charging, to the discharging phases of the storage system.

What is a compressed air storage system?

The compressed air storages built above the ground are designed from steel. These types of storage systems can be installed everywhere, and they also tend to produce a higher energy density. The initial capital cost for above- the-ground storage systems are very high.

What are the advantages of compressed air energy storage systems?

One of the main advantages of Compressed Air Energy Storage systems is that they can be integrated with renewable sources of energy, such as wind or solar power.

During the charging process, a water pump drives a liquid piston to compress the gas for energy storage. The compressed gas expands during discharging, facilitating the liquid to drive a water turbine to generate electricity. As a result, a round-trip efficiency of 82 % and an energy storage density of 3.59 MJ/m<sup>3</sup> can be achieved.
