

What does energy storage peak load regulation and frequency regulation mean

What is frequency regulation?

Frequency regulation is the process of balancing the supply and demand of electricity to maintain this consistent frequency. Frequency regulation involves real-time adjustments to the power grid to counteract fluctuations in electricity supply and demand. Here's a closer look at how this process works:

What is the multi-timescale regulation capability of a power system?

The multi-timescale regulation capability of the power system (peak and frequency regulation, etc.) is supported by flexible resources, whose capacity requirements depend on renewable energy sources and load power uncertainty characteristics.

What is the power and capacity of ES peaking demand?

Taking the 49.5% RE penetration system as an example, the power and capacity of the ES peaking demand at a 90% confidence level are 1358 MW and 4122 MWh, respectively, while the power and capacity of the ES frequency regulation demand are 478 MW and 47 MWh, respectively.

Why is frequency regulation important in modern power system?

In modern power system, the frequency regulation (FR) has become one of the most crucial challenges compared to conventional system because the inertia is reduced and both generation and demand are stochastic.

Does ES capacity enhance peak shaving and frequency regulation capacity?

However, the demand for ES capacity to enhance the peak shaving and frequency regulation capability of power systems with high penetration of RE has not been clarified at present. In this context, this study provides an approach to analyzing the ES demand capacity for peak shaving and frequency regulation.

What is the demand power for frequency regulation of ES?

The demand power for frequency regulation of ES for the four penetration scenarios is 203 MW, 290 MW, 483 MW, and 702 MW at 90% of the confidence level, which is equivalent to 1.68%, 2.22%, 3.41%, and 4.53% of the total installed system capacity respectively.

In the energy market, high levels of participation will mean significantly reduced load during peak hours, which is the goal of the peak reduction strategy. The problem with this, however, is that lower loads translate into lower electricity prices during the times that V2G participants will be selling their energy to the grid.

These are frequency regulation and net load regulation. Frequency regulation is implemented according to classical droop control (where $Df = f_0 - f$, being f_0 the nominal frequency of the power system). The scope of the net load regulation is to contain the net load of the micro distribution grid between 100 kW and 400 kW.

The penetration of the renewables increases all over the world, which brings challenge to the frequency stability of the power system.
